The building blocks that go to make up our bodies are iron, calcium, carbon, hydrogen and oxygen, just to name a few. Each part of the body plays a unique role and works together. If one part of the body malfunctions, the body as a whole cannot function properly. When a person develops an injury, the body has the ability to repair the injury, however it cannot do so without replacing or regenerating the damaged tissue. Injuries that are more severe or a long time can develop into degenerative diseases that cause the loss of structure and function of the body. In an effort to advance in understanding of the body's natural repair mechanisms and regenerative capabilities, scientists have been able to develop methods to artificially induce stem cells to regenerate entire body parts. Orthopedic medicine is in the early stages of developing methods to recover lost body parts, many of which are complicated and require amputation of the original body part and its insertion of an artificial replacement. Orthopedic Medicine Background Orthopedic medicine is a subspecialty of the medical field that deals with correcting and treating disorders or injuries to the musculoskeletal system. This system includes: muscles, bones, joints, ligaments, tendons and other supporting structures. Orthopedic diseases and disorders are widely known and include, for example: arthritis, bone injuries, spinal cord injuries, congenital deformities, leg amputations, unrepairable fractures, and osteoporosis. The field of orthopedics also includes the creation of prosthetics to replace parts of the body that are missing or have been damaged. Orthopedic treatments involve, for example, casting, exercises, splints, braces, pins, screws, plates, and minimally invasive surgeries (MIS) including, for example, single-site, single-anesthesia, and percutaneous surgery. Although the field of orthoped
